Abstract

Early mortality in Duchenne muscular dystrophy (DMD) is related to cardiac and respiratory complications. A phase IIa double-blind randomized placebo-controlled clinical trial was conducted to investigate the tolerability and efficacy of idebenone therapy in children with DMD. Twenty-one DMD patients (aged 8–16 years) were randomly assigned to daily treatment with 450 mg idebenone (Catena®) ($n = 13$) or placebo ($n = 8$) for 12 months. All subjects completed the study and idebenone was safe and well tolerated. Idebenone treatment resulted in a trend ($p = 0.067$) to increase peak systolic radial strain in the left ventricular inferolateral wall, the region of the heart that is

earliest and most severely affected in DMD. A significant respiratory treatment effect on peak expiratory flow was observed ($p = 0.039$ for PEF and $p = 0.042$ for PEF percent predicted). Limitations of this study were the small sample size, and a skewed age distribution between treatment groups. Data from this study provided the basis for the planning of a confirmatory study.
