Abstract: Between September, 1962, and July, 1963, chlorinated hydrocarbon pesticides were found in 304 of 333 birds and 42 of 46 egg samples sent from different parts of Great Britain and Eire, and mercury residues in 55 of 142 birds. Sixty-six species were affected. Sources of the parasiticides were considered to be garden chemicals in 154
in 59, and seed dressings in 45. Compared with previous years, there were increases in the casualties in insectivorous and garden species, species feeding in flowing or standing water and marsh areas, and birds of prey. Chlorinated hydrocarbon were detected in all of 19 broods of nestlings that died in the nest, in all of 7 samples of worms and land treated with aldrin, and in leeches and fishes from a small pond. Deaths from seed dressings have declined as a result of the voluntary restriction on their use, but deaths from other applications such as spraying are increasing. It was concluded that persistent chlorinated hydrocarbons be banned in gardens, forests and waters.
