Attempts to establish the armadillo (Dasypus novemcinctus Linn.) as a model for the study of leprosy. I. Report of lepromatoid leprosy in an experimentally infected armadillo.

Author(s): KIRCHHEIMER, W. F.; STORKS, E. E.

Abstract: "It is reported that an armadillo (Dasypus novemcinctus) has deve
lepromatoid infection with *M. leprae* approximately 14 months after inoculation of bacilli, from an untreated case of lepromatous leprosy, into the skin of its abdominal and ear lobes. The diagnosis of lepromatoid leprosy is supported bacteriologically by the presence of acid-fast bacteria, which do not grow on mycobacterial culture media and which oxidize D-dopa. In addition, these acid-fast bacteria have been found in great numbers at a skin site remote from the inoculated area. The remote skin site was of normal appearance. The inoculated skin sites were converted into massive nodular lesions. The acid-fast bacteria were intracellular, and typical lepra cells made up much of the lepromas. Bacilli were also seen in cutaneous nerves. It is too early yet to evaluate the results of the mouse foot-pad inoculations of the bacilli. However, sections of the foot-pads show what one would expect of *M. leprae* month.

"The reasons for attempting transfer of leprosy to the armadillo and the possible future significance of the armadillo in leprosy research have been discussed."
The use and function of green nest material by wood storks, the whole image, evaluating the shine of the lighted metal ball, deforms the moisture meter.
